WATER - LEVEL DATA FROM  
OBSERVATION WELLS IN THE  
NORTHWESTERN GULF COASTAL  
PLAIN OF TEXAS

INTRODUCTION

This publication contains water-level data from observation wells in nine counties of the northwestern Gulf Coastal Plain of Texas, an area of approximately 10,000 square miles shown on page 2. This area includes the heavily pumped Winter Garden irrigation district, and adjacent areas in which considerable water-level data have been gathered. The water-level and related data are presented in the form of county tabulations, location maps, and hydrographs of selected representative observation wells. The wells are part of the statewide network of observation wells measured and recorded by personnel of the Texas Water Development Board.

Evaluation of water-level records is an important part of every ground-water investigation. Water-level records reflect any change in the amount of water in underground storage, as well as the direction and rate of water movement. Excessive decline of water levels may increase pumping costs, decrease well yields, and cause abandonment of some shallow wells; in some areas it may also cause ground water of poor quality to move toward the wells. Measurements of water-levels in carefully selected wells are therefore essential in order to better understand ground water conditions.

WATER-LEVEL OBSERVATION PROGRAM

Observation wells are measured by the Texas Water Development Board in various areas of the State to observe changes in water levels in the principal aquifers or water-bearing formations. The Board's water-level observation program includes the following: (1) selecting, in every major aquifer, a network of wells that are spaced to afford adequate data for preparation of piezometric maps or water-table contour maps; (2) measuring water levels periodically in each well in this network, at the time of year when water levels have recovered from the effect of pumping during the season of peak water demand; (3) installing automatic recorders in a few representative wells to provide a continuous record of water-level changes; (4) preparing maps and graphs that show the fluctuation of water levels as revealed by water-level measurement, and (5) evaluating and publishing water-level information.

Map of Texas Showing Area Covered by This Report  
 Texas Water Development Board

Prior to September 1960, the program of observing water levels in Texas was conducted by the U.S. Geological Survey in cooperation with the Texas Water Development Board; since then, a major part of the program has been administered by the Board. The water-level observation activities of the Board are performed by personnel of the Basic Hydrologic Data Division, under the general direction of John J. Vandertulip, Chief Engineer, C. R. Baskin, Assistant Chief Engineer, and Jack W. Stearman, Director of the Basic Hydrologic Data Division.

The following personnel of the Texas Water Development Board have participated in the collection and compilation of data for the nine-county area of the northwestern Gulf Coastal Plain of Texas:

Curtis Andrews	Tom Lanier
Hershel Davidson	Ralph Muse
Charles Ferguson	Harold Phipps
James Fisher	Jerry Skrabanek

Tabulations of water-level data contained in this report were prepared by the Electronic Data Processing Division of the Texas Water Development Board.

Acknowledgement and appreciation is extended to the landowners in the report area for their interest and cooperation in the water-level observation program.

#### METHODS OF COLLECTING WATER-LEVEL DATA

Water levels in most of the observation wells are measured annually. If possible, wells selected for annual observation should not be equipped with a pump and should not be close to heavily pumped wells. In areas of intense ground-water development, however, usually the only wells available for measurements are equipped with large-capacity turbine pumps. In these wells, measurements of water levels should be made during periods of lowest seasonal pumping (generally the winter months) when water levels will be more representative of the surrounding area.

Water levels are reported as depth to water below land surface. This depth is obtained by measuring the distance from a permanent measuring point near the land surface to the water level in the well. The vertical distance between the measuring point and the land surface is then subtracted and distance from land surface to water is obtained. Water-level measurements are made by one of the following methods:

##### (1) Wetted Steel Tape Method

A calibrated steel tape, chalked on its lower end to make the wetted portion visible, is lowered into the well. The depth to water below the well's measuring point is obtained by subtracting the wetted portion at the lower end of the tape from the tape reading at the well's measuring point.

Water levels measured with a steel tape are recorded to the nearest hundredth of a foot. The wetted steel tape method for obtaining water-level measurements is considered the most accurate, and is the method commonly used by the Texas Water Development Board.

## (2) Electric-Line Method

The electric line measuring device consists of a hand-operated reel, a current meter, a dry-cell battery for power, and a length of double-conductor insulated wire with an electrode at the end. The electric line operates on the principle of a completed electric circuit. When the electrode on the end of the electric line contacts the water surface in the well, the electric circuit is completed and is indicated on the current meter at land surface. Calibrated markings on the electric line provide a means for direct reading of the depth to water.

Water-level measurements obtained by this method are recorded to the nearest tenth of a foot. The electric-line method is used where water-level measurements cannot be made with a steel tape, such as wells having leaky casings.

## (3) Air-Line Method

An air line is a metal tube attached to the outside of the pump column and extending from the pump base to some known precise depth that is below the lowest water level to be measured. The air line is equipped with a pressure gage and an ordinary tire valve, which are attached to some convenient place on the pump. The pressure required to force all of the water out of the air line is equal to the pressure exerted by the column of water standing outside the air line. Some air-line gages read directly in feet of water; others read in pounds per square inch and must be converted to feet of water by multiplying the gage reading by 2.31. In both instances the result must be subtracted from the known vertical air-line length to determine the depth to water from the center of the gage. Air lines are most commonly installed on industrial and municipal wells that have large-capacity turbine pumps.

Water-level measurements obtained by the air-line method are recorded to the nearest foot. This method cannot be used reliably where more precise measurements are required. However, the air-line method can be used in wells that otherwise could not be conveniently measured, such as wells that are pumping and those that are sealed to keep out surface contaminants.

## (4) Automatic Recorder Method

An automatic water-level recorder consists of a float on the water surface, a clock-driven recording chart installed over the well, and a metal tape or cable connecting them. As the float rises and falls with the water surface in the well, the motion is transferred to a pen which graphs the fluctuation on the chart. This continuous recording is best suited for measuring rapid or irregular fluctuations in areas of large ground-water withdrawals.

Recorders are visited frequently for maintenance, accuracy checks, and collecting water-level records. Water-level readings taken from the recorder charts are generally tabulated to the nearest hundredth of a foot.

## (5) Flowing Wells

When measuring water levels in flowing wells (water level above land surface), the well must be shut-in so that the static pressure can be observed at some convenient measuring point near the ground. The static pressure is then converted to feet to determine the water level above land surface.

Flowing wells can be measured with a pressure gage, a mercury U-tube manometer, or a water manometer.

The accuracy in determining the shut-in pressure of flowing wells is considerably less than the accuracy obtained when measuring water levels below land surface. Most pressure gages cannot be read more accurately than to the nearest foot. Furthermore, unless the well is shut-in for a sufficient period of time, the measured pressure will be somewhat less than the true static pressure. Pressure measurements are recorded to the nearest foot.

#### PRESENTATION OF DATA

The following information is recorded in the field on standard forms for each observation well checked by the Texas Water Development Board: the water-level measurement, date of measurement, pertinent remarks, and initials of the person making the measurement. The field data are later transferred to punch cards which enable the water-level measurements to be statistically analyzed. The results are then printed in a concise tabular form by computers and other data processors.

Tables in this report provide the following information: well number, depth of well, elevation of land surface in feet above mean sea level, dates of measurement, measurements of water level in feet below land surface, and changes (decline or rise) in water level from the previous year's measurement. These tables are reproduced from direct printouts of electronic data processing equipment.

Preceding the table for each county is a well-location map. Hydrographs, showing changes in water levels, are presented for selected representative wells following the respective county tabulations.

#### WELL-NUMBERING SYSTEM

The wells in this report are numbered according to a statewide well-numbering system, in which quadrangles formed by degrees of latitude and longitude are subdivided into smaller quadrangles, as shown on the following page.

Each 1-degree quadrangle is divided into sixty-four  $7\frac{1}{2}$ -minute quadrangles, and each of these in turn is divided into nine  $2\frac{1}{2}$ -minute quadrangles. Each 1-degree quadrangle in the State has been assigned an identification number. The sixty-four  $7\frac{1}{2}$ -minute quadrangles are numbered consecutively from left to right, beginning in the upper left-hand corner of the 1-degree quadrangle, and the nine  $2\frac{1}{2}$ -minute quadrangles within the  $7\frac{1}{2}$ -minute quadrangles are similarly numbered. A well number consists of seven digits: the first 2 digits identify the 1-degree quadrangle; the 3rd and 4th, the  $7\frac{1}{2}$ -minute quadrangle; the 5th digit identifies the  $2\frac{1}{2}$ -minute quadrangle; and the last 2 digits identify the well within the  $2\frac{1}{2}$ -minute quadrangle.

On the well location maps in this report, only the last three digits of the well numbers are shown beside the well symbols; the 1-degree quadrangles are numbered with large open-block numerals, and the  $7\frac{1}{2}$ -minute quadrangles are numbered in their northwest corners.

1-degree Quadrangles

Location of Well 57-15-701

- 57 1-degree quadrangle
- 15 7 1/2-minute quadrangle
- 7 2 1/2-minute quadrangle
- 01 Well number within 2 1/2-minute quadrangle

7 1/2-minute Quadrangles

2 1/2-minute Quadrangles

Well - Numbering System

## FLUCTUATIONS OF WATER LEVELS

Changes in water levels are due to many causes. Some are of regional significance, whereas others are local. Variations in aquifer recharge (ground-water replenishment) or discharge (ground-water loss) are the main causes of the regional water-level changes. Thus, changes in water levels reflect the changes in the amount of water stored in an aquifer.

When a water well is pumped, the water table (or the piezometric surface in an artesian aquifer) in the vicinity of the well is drawn down in the shape of an inverted cone with its apex at the pumped well. This cone is commonly referred to as the cone of depression. The rate of growth of this cone depends on the characteristics of the aquifer and on the rate of pumping; in areas where recharge is continually less than the amount of water pumped, water levels will continue to decline.

Where many closely spaced wells pump water from an aquifer, the cones of depression formed by the individual wells may overlap so as to form a wide-spread, regional cone of depression. In such an area, the rate of decline of water levels is related to the pumping rate of each well, the spacing of wells, and the characteristics of the aquifer.
